

# Simple Geometry

# Materials & Dimensions

- 1.1 m radius cylinder with 3.2 m length
- **water**, Fe, Pb, C, CH<sub>2</sub>, NaCl, CaCO<sub>3</sub>
- density 1 g/cm<sup>3</sup>, for water, standardized for others and will be placed in table on AARM wiki.
- Energies **280 GeV**, 10 GeV, 30 GeV, 100 GeV, 1 TeV
- **$\mu^-$** ,  $\mu^+$

# Physics Lists & Geant4 Versions

- Initially Geant4.9.3 used without Shielding list or  $\mu$ -Nuclear
- Next Move on to Geant4.9.3 with Shielding and  $\mu$ -Nuclear included (Dennis Wright port)
- Next use Geant4.9.4 with  $\mu$ -Nuclear

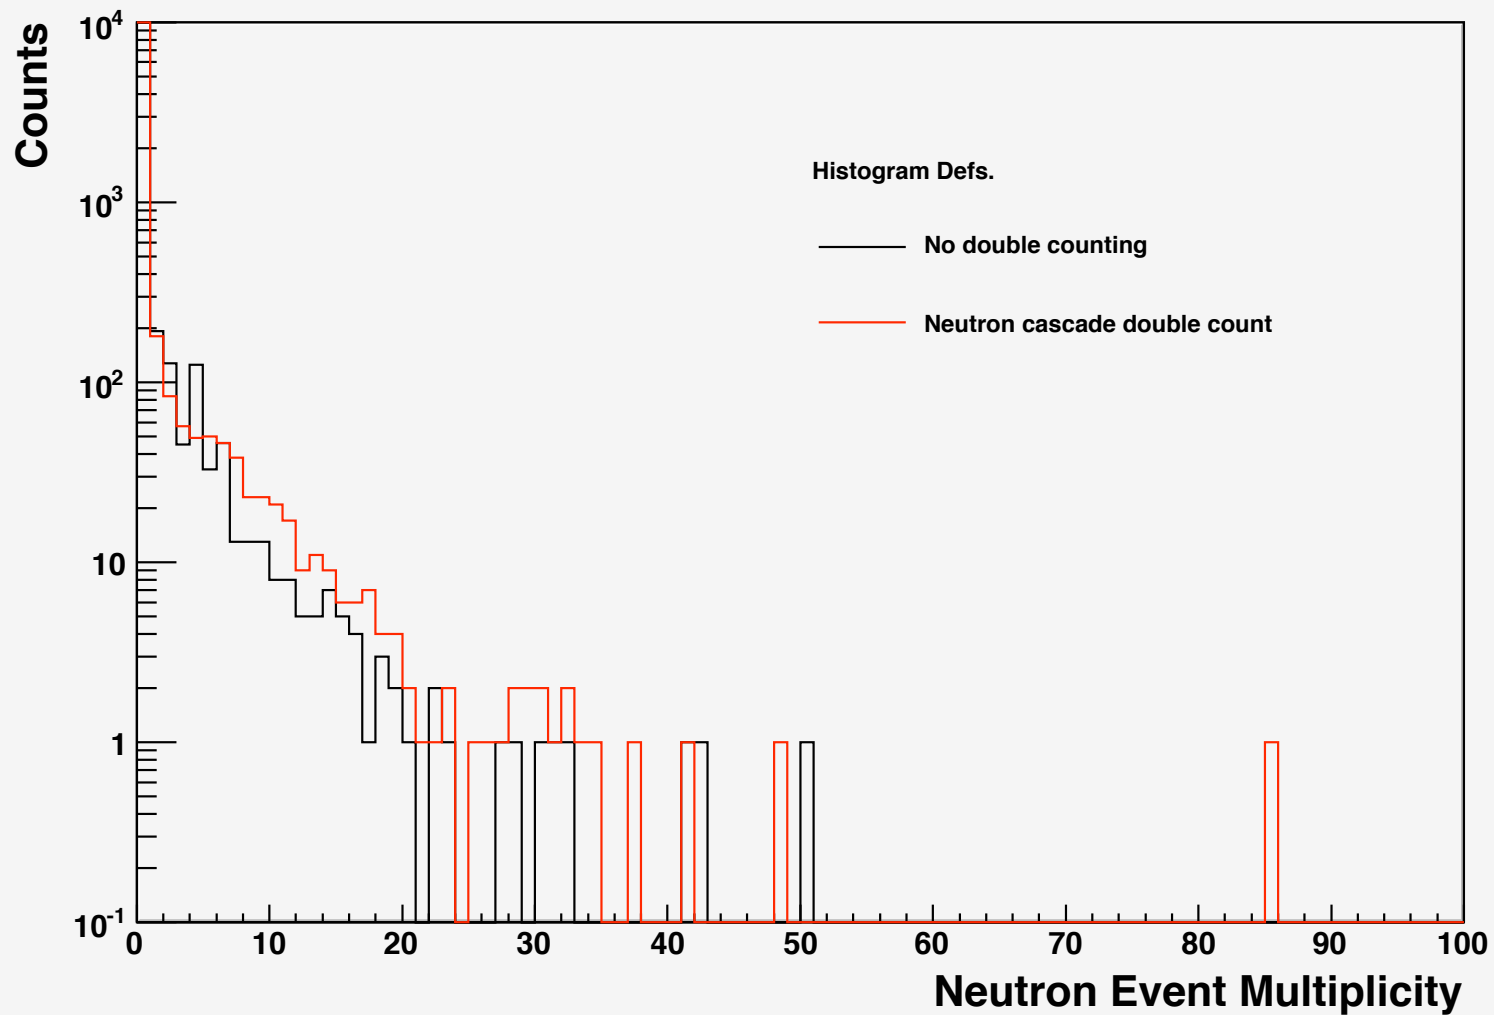

# Fiducialization & Counting

- For water inner 1.0 m radius and 1.2 m length sensitive det.
- All particle interactions are tracked and every track is retained
- The above requires 14 Gb per 10,000 primaries in plain text
- 10,000 primaries run in 111 minutes on a single dual-core processor
- Should probably find a way to reduce the retained data one way is to throw away most of the  $\mu$  hits in the sensitive detector since they basically go straight
- The full tracking should allow (with some carefully made algorithms) to avoid the “double counting” issue which has been mentioned

# ...But Large!

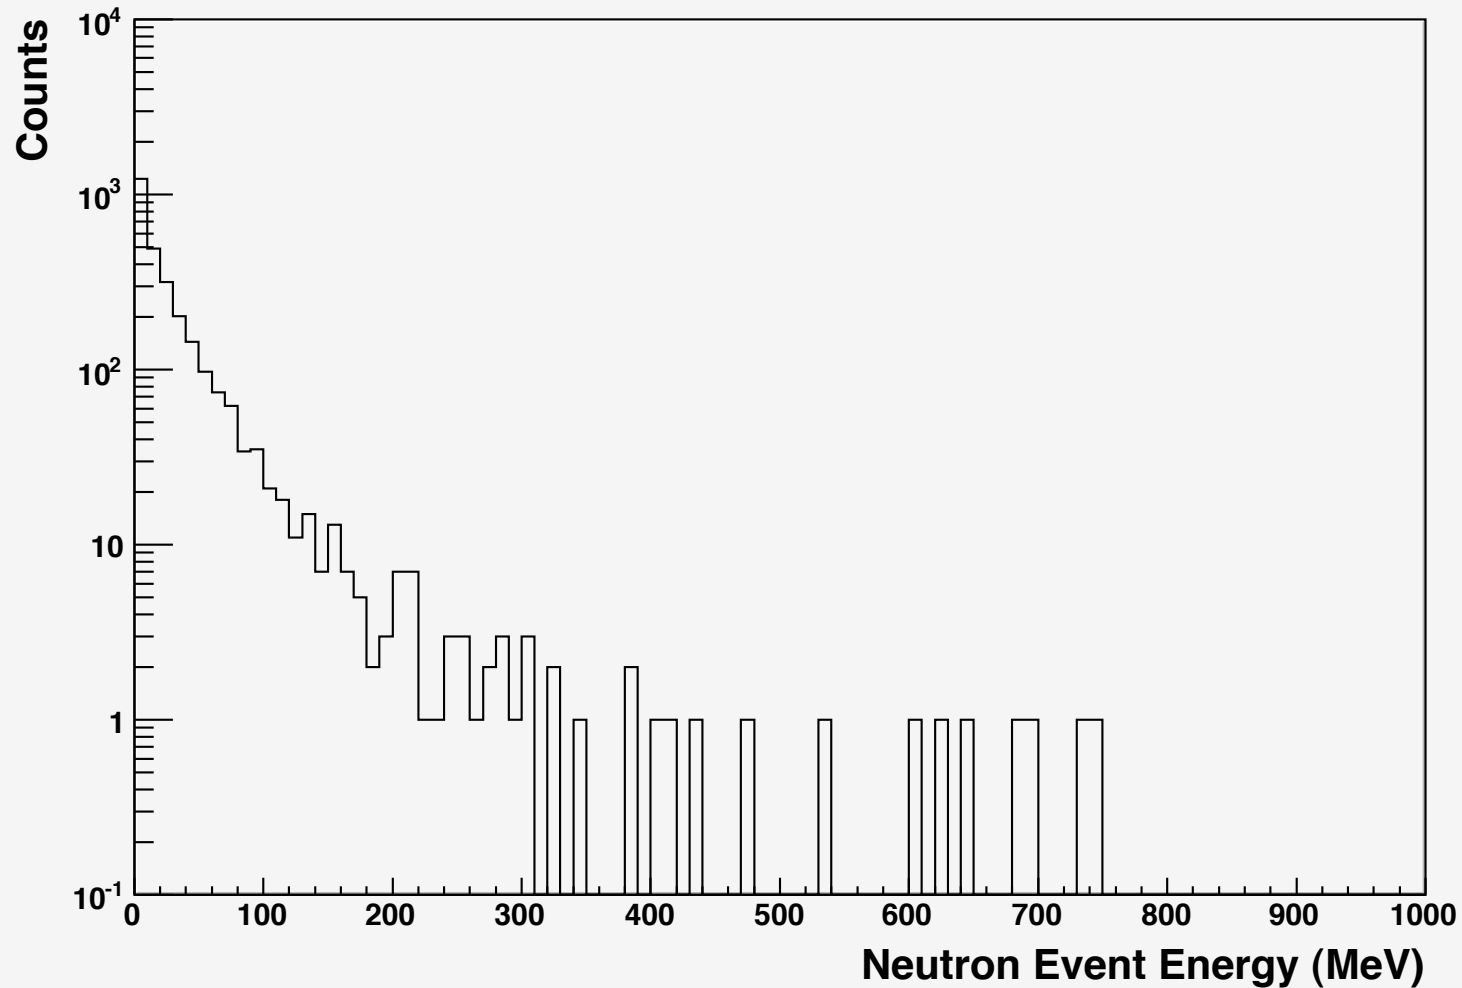

## Neutron Event Multiplicity

# Neutron Start Energies (10k Ev.)

Neutron Energy

# Status & Direction

- Using Geant4.9.3 without “Shielding” physics list or  $\mu$ -Nuclear
- Ran 50,000 primaries with  $\text{H}_2\text{O}$  and full tracking  $\sim 200$  Gb
- Fiducial volume unsegmented sensitive detector
- All vertices can be fully reconstructed
- Cut out 90 – 95% of pure  $\mu$  events to save space
- Run  $\sim 500,000$  primaries on each configuration and energy originally suggested
- Compile Geant4.9.4 and “special” Geant4.9.3+Shielding+ $\mu$ -Nuclear at University of Minnesota and run previous sets
- Continue to identify the best observables both for large scale assessments of neutron fluxes and for comparison to microscopic interaction data.
- Compare all data to Fluka (via. Toni Empl)
